```
1 <?php
2 $docRoot = $_SERVER['DOCUMENT_ROOT'];
3 $uploadDir = $docRoot . "/" . "upload";
4 if(!is_dir($uploadDir)){
5     mkdir($uploadDir);
6 }
7
8 if( $_FILES['file']['name'] != "" ){
9     move_uploaded_file( $_FILES['file']
10         die( "檔案上傳失敗");
11 } else {
12     die("開啟檔案失敗!");
13 }

## Transaction - ACID

**Atomicity** requires that each transaction be "all or nothing": if one part of the transaction fails, the entire transaction fails, and the database state is left unchanged. (不可分割性)

**Consistency** ensures that any transaction will bring the database from one valid state to another. Any data written to the database must be valid according to all defined rules, including constraints, cascades, triggers. (一致性)

**Isolation** ensures that the concurrent execution of transactions result in a system state that would be obtained if transactions were executed serially, i.e. one after the other. (隔離性)

**Durability** means that once a transaction has been committed, it will remain so, even in the event of power loss, crashes, or errors. (永久性)

## Limitations for SQL database

### 擴充困難 Scability

**Scalability:** Users have to scale relational database on powerful servers that are expensive and difficult to handle. To scale relational database it has to be distributed on to multiple servers. Handling tables across different servers is a chaos.

### 設計複雜 Complexity

**Complexity:** In SQL server's data has to fit into tables anyhow. If your data doesn't fit into tables, then you need to design your database structure that will be complex and again difficult to handle.

## What is Big Data?

Big data means immense amount of data, so much so that it is difficult to collect, store, manage, and analyze via general database software. In general, the meaning of “immense amount of data” is classified into three types as follows:

- **Volume:** There is too much data to be stored and require too many processes—semantic analysis/data processing. These are the two elements that we need to understand.
- **Velocity:** It means storage and processing speed.
- **Variety:** The demand for unstructured data, such as text and images is increasing as well as refined-type data that can be standardized and previously defined like the RDBMS table record.

# 雲端資料庫基本原理-CAP 理論 01

---

According to [University of California, Berkeley](#) computer scientist [Eric Brewer](#), the theorem first appeared in fall 1998.<sup>[4]</sup> It was published as CAP principle in 1999.

In 2002, [Seth Gilbert](#) and [Nancy Lynch](#) of [MIT](#) published a formal proof of Brewer's conjecture, rendering it a [theorem](#).

## 資料亂掉

**Consistency** - This means that the data in the database remains consistent after the execution of an operation.

## 主機當機

**Availability** - This means that the system is always on (Service guarantee availability), no downtime.

## 網路斷線

**Partition Tolerance** - This means that the system continues to function even if the communication among the servers is unreliable, i.e. the servers may be partitioned into multiple groups that cannot communicate with one another.

# 雲端資料庫基本原理-CAP 理論 03

# 雲端資料庫基本原理-CAP 理論 04

---

Generally, it is not possible to fulfill all three requirements in a distributed system. **不可能完全滿足 CAP 三項要求**

CAP provides the basic requirements for a distributed system to follow two of the three requirements. **最多只能滿足 CAP 其中二項要求**

Distributed systems must be partition tolerant (P), so we have to choose between Consistency and Availability. **分散式系統一定要滿足 P 項的要求**

Current NoSQL databases follow the different combinations of C and A from the CAP theorem. **NoSQL 可以滿足 AP 項或 CP 項要求**

**RDBMS (傳統資料庫)**

**Relational Database Management System (SQL)**  
**(SQL-Structured Query Language)**

**NoSQL (雲端資料庫)**

**Not only SQL**

# RDBMS and NoSQL-選擇資料庫 02

---

If SQL is your only storage tool, then all problems must look the same – no Big Data.

Using SQL and NoSQL storage technologies where appropriate, systems can have

**SQL 高一致性**

- SQL for high **consistency** where needed

**NoSQL 高可用性與擴充性**

- NoSQL for high **availability and scalability**

# RDBMS and NoSQL-選擇資料庫 03

---

In the business world -

實務應用上，高可用性比高一致性更重要

**Availability** is **more valuable** than **Consistency**

可以替代查詢其他表格資料(例如訂單)、道歉、或修補

– When in doubt, take the customer's order.

– Apologize, fix, and compensate later.

但千萬不要對客戶說很抱歉，機器當掉所以無法向您收費

**Do not say**

**Sorry, we can not take your money.**

**Our computers are down!**

# RDBMS and NoSQL-選擇資料庫 04

---

NoSQL databases relaxed the ACID properties (**BASE**)

基本上一定可以使用

**Basically Available:** The database system always seems to work!

資料不一定隨時一致

**Soft State:** It does not have to be consistent all the time

但資料最後一定一致

**Eventually Consistent:** The system will eventually become consistent when the updates propagate, in particular, when there are not too many updates

# RDBMS and NoSQL-選擇資料庫 05

---

- Structured and organized data **RDBMS**
  - Structured query language (SQL)
  - Data and its relationships are stored in separate tables.
  - Data Manipulation Language, Data Definition Language
  - Tight Consistency and ACID Transaction
- 
- Unstructured and unpredictable data and Big Data **NOSQL**
  - No declarative query language
  - CAP Theorem and No predefined schema
  - Key-Value Store, Column Store, Document Store and Graph Store
  - Eventual consistency rather than ACID property
  - Prioritizes high performance, high availability and scalability

# RDBMS and NoSQL-選擇資料庫 06
